**1970 - First AI Winter**

AI was subject to critiques and financial setbacks. AI researchers had failed to appreciate the difficulty of the problems they faced.

AI was claimed to only be suitable for solving "toy" versions.

**1970**

# Deep Learning Timeline - 2

1980

**Kunihiko Fukushima** creates Neocognitron, an artificial neural network that learned how to recognize visual patterns.

His work led to the development of the first convolutional neural networks, which are based on the visual cortex organization found in animals.

1980

# Deep Learning Timeline - 2

**1980**

**Kunihiko Fukushima** creates Neocognitron, an artificial neural network that learned how to recognize visual patterns.

His work led to the development of the first convolutional neural networks, which are based on the visual cortex organization found in animals.

**1980**

**1987**

## **1987 - Second AI Winter**

Many AI projects expectations had run much higher than what was actually possible.

Over 300 AI companies had shutdown, gone bankrupt, or been acquired by the end of 1993, effectively ending the first commercial wave of AI.

# What is Possible With Deep Learning?

---

# Deep Learning Applications

- Supervised learning tasks
- Object Recognition – Seeing:

- Speech Recognition and NLP – Hearing and understanding text:

- And now we try to teach them creativity:
  - Music and Text Generation
  - Neural Style Transfer:

■ ...

# How Deep Learning Works

---

# The Perceptron

- The perceptron was invented by Frank Rosenblatt 1957.

The Mark I Perceptron

- It is the basic computational unit for neural networks.

# Singlelayer Perceptron

- Weighted sum of input values transformed by an activation function  $s$
- If  $s$  is the sigmoid function  $(1 + \exp \sum)^{-1}$ , then the perceptron does exactly the same as the logistic regression

# Multilayer Perceptron

- Stacking of multiple perceptrons
- Corresponds to stacking GLM models
- Number of parameter grows very fast  
→ Optimization becomes more difficult

# Optimizer

- Having that much parameter/weights to find, standard optimizer like Gradient Descent may fail
- Therefore, much effort was spend to get faster optimizer like adam, rmsprop, etc.:

**Source:** Ruder, S. (2016). An overview of gradient descent optimization algorithms. arXiv preprint arXiv:1609.04747.

# Convolution

- Generating of new, hopefully meaningful, features of the input (commonly images)

# Convolution

Input Image

Generated Image/Feature

**Note:** The recognition of edges and corners requires a multiple application of the operator.

# Pooling

Down-sampling of images:

- Less weights to fit
  - Smaller net size (less memory usage, faster fitting process)
  - Reduces overfitting

# Lets Get Deep

- The power of Deep Neural Nets comes from chaining hidden layer such as convolution layers, pooling layers, and so on
- This deep structure allows the network to create powerful features and explore complex structures within the data
- VGG16 architecture:

# Challenges in Deep Learning

---

- **Finding a Good Architecture**

Having that many possibilities of combining hidden layer, optimizer, and activation functions we run into the problem of finding a good architecture.

- Transfer learning, use already trained models, adjust them to your data situation, and train (a subset of) the weights.
- Architecture search

- **Expensive Training**

Training of DNNs require billions of simple operations, hence training **one** DNN might take weeks.

- Use GPU server for serious applications. Why? See next slides.

# Tech Stack

---

# Hardware

- Deep Neural Networks require special hardware to be trained efficiently.
- The training is done using **Graphics Processing Units** and a special programming language called **CUDA**.
- Training on standard CPUs takes a very long long time and gets infeasible for anything but toy examples.

Each CPU can do 2 – 8 parallel computations.

A single GPU can do thousands of simple parallel computations.

CUDA is a very **low level** programming language and thus writing code for Deep Learning requires a lot of work. Software projects, like TensorFlow and abstract CUDA provide additional functionality.

The basic concept of calculations in deep neural networks is a *computational graph*, which describes the dependency structure of the network.

Computational graph for  $f(XW + b)$ .

- Open-source framework developed by google.
- Rather low-level and aimed to directly work with computational graphs.
- Mainly support for Python (R support only via *reticulate*).
- Widely used and well documented.

- Open-source high-level API for Deep Learning.
- Can run on top of **TensorFlow**, CNTK or Theano.
- Mainly support for Python (R support only via **reticulate**).
- Widely used and well documented.

# Keras in R

- Deep learning in R is the same as in Python.
- Communication from R to Python via **reticulate**.

- Syntax is (almost) identical.
- Same functionality.
- Same speed (slight overhead for communication between R and Python).
- More difficult to debug.

Useful resources:

<https://keras.rstudio.com/>

<https://rstudio.github.io/reticulate/articles/introduction.html>

- Open-source framework developed by facebook.
- Reimplementation of Torch.
- Only support for Python.
- Widely used and well documented.

- Open-source high-level API build on top of PyTorch.
- Still in alpha version.
- Only support for Python.
- Initially developed for the *Practical Deep Learning for Coders* online course.

- Open-source framework in the Apache foundation.
- Scalable, allow easy training on multiple GPUs in parallel.
- Supports multiple languages (C++, Python, R, Julia, Matlab, JavaScript, Go, Scala, Pearl).
- Not as widely used as other frameworks.

# Where to Start in the DL Jungle

---

# Getting Started with Keras - Installation

Install keras using pip (or pip3 for python3) from the command line:

```
# python
```

```
pip install --upgrade tensorflow
```

```
pip install keras
```

```
# python3
```

```
pip3 install --upgrade tensorflow
```

```
pip3 install keras
```

On linux you may need to run the commands as sudo.

# Getting Started with Keras - Overview

- Instead of introducing theory, we want to get into the topic by applying it.
- We use examples similar to the book **Deep Learning with Python** that are prepared as **notebooks**.
- **But:** When using something new, e.g. a convolution layer or optimizer, try to understand what it does and why it might be beneficial!
- First of all, we have to load keras and import models and layers:

```
import keras # equal to Rs library command  
from keras import models  
from keras import layers
```

# Gettins Started with Keras - Example Data 1

```
import numpy as np
from keras.datasets import cifar10 # Our dataset
# See https://www.cs.toronto.edu/~kriz/cifar.html

(X_train, Y_train), (X_test, Y_test) = cifar10.load_data()
X_train.shape
## (50000, 32, 32, 3)

categories = ["airplane", "automobile", "bird", "cat",
              "deer", "dog", "frog", "horse", "ship",
              "truck"]

import matplotlib.pyplot as plt

category = categories[np.asscalar(Y_train[2305])]
plt.title('Label is \"{label}\"'.format(label=category))
plt.imshow(X_train[2305], cmap='gray')
plt.show()
```

## Getting Started with Keras - Example Data 2

## Getting Started with Keras - Example Data 3

The images are represented as rgb colors, each of the  $32 \times 32$  pixels is represented as three numbers between 0 and 255. For the training we want to use values between 0 and 1:

```
train_images = X_train.astype('float32') / 255  
test_images = X_test.astype('float32') / 255
```

Additionally, we have to convert the labels to a categorical data type:

```
from keras.utils import to_categorical  
  
train_labels = to_categorical(Y_train)  
test_labels = to_categorical(Y_test)
```

# Getting Started with Keras - DNN 1

```
network = models.Sequential()

network.add(layers.Conv2D(64, (3, 3),
                          input_shape=(32, 32, 3), padding='same',))
# now: model.output_shape == (None, 64, 32, 32)

network.add(layers.Flatten())

# Add fully connected hidden layer:
network.add(layers.Dense(units=128,
                          activation='relu'))

# Add output layer which maps each category to a neuron:
network.add(layers.Dense(10, activation='softmax'))

# Make the network ready for training:
network.compile(optimizer='rmsprop',
                loss='categorical_crossentropy',
                metrics=['accuracy'])
```

# Getting Started with Keras - DNN 2

```
network.summary()
```

```
## -----  
## Layer (type)                Output Shape          Param #

##
```

# Getting Started with Keras - DNN 3

*# Train network:*

```
network.fit(train_images, train_labels, epochs=5, batch_size=128)
```

```
network.evaluate(test_images, test_labels)
```

*## [1.5289124059677124, 0.4727]*

# Getting Started with Keras - DNN 4

Now we try to predict the class of a new image. Therefore, we have to rescale the original image to the same input shape of the training images:

Original Image of Wuschel  
(a cat)

Rescaled Image of Wuschel  
(still a cat, but very blurred)

# Getting Started with Keras - DNN 5

```
from keras.preprocessing.image import load_img, img_to_array
img = load_img('wuschel.jpg', target_size=(32, 32))
img = img_to_array(img).astype('float32') / 255

plt.title('This is Wuschel')
plt.imshow(img, cmap='gray')
plt.show()
```

# Getting Started with Keras - DNN 6

```
wuschel_pred = network.predict(np.array([img]))
wuschel_pred
## array([[0.01510279, 0.03711035, 0.04978644, 0.25755176,
