What is Deep Learning

The Big Picture - From History to Todays Implementations

Daniel Schalk October 23, 2018

History of Deep Learning

1943

Warren S. McCulloch and Walter Pitts published tried to understand how the brain could produce highly complex patterns by using many basic cells that are connected together.

1957

Frank Rosenblatt declared that he construct a system which works similar to the perceptual processes of a biological brain - The Perceptron.

Alexey Ivakhnenko and V. G. Lapa created the first working deep learning networks, applying what had been only theories and ideas up to that point.

Ivakhnenko developed a learning algorithm using deep feedforward multilayer perceptrons. For that reason alone, many consider Ivakhnenko the father of modern deep learning.

1970 - First Al Winter

Al was subject to critiques and financial setbacks. Al researchers had failed to appreciate the difficulty of the problems they faced.

Al was claimed to only be suitable for solving "toy" versions.

Fascination Deep Learning

Imitating Humans - 1

Turing test:

- Developed by Alan Turing in 1950
- Test of a machine's ability to exhibit intelligent behavior
- Player C, the interrogator, is given the task of trying to determine which player, A or B, is a computer and which is a human

Imitating Humans - 2

Image Recognition (Seeing):

 Speech Recognition and Text Mining (Hearing and understanding text):

Imitating Humans - 3

- And know we try to learn them being creative:
 - Music and Text Generation
 - Neural Style Transfer:

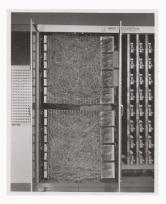

• . .

Why Deep Learning is so Powerful?

The Perceptron

• The perceptron was invented by Frank Rosenblatt 1957.

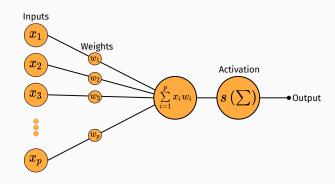

The Mark I Perceptron

It is the basic computational unit for neural networks.

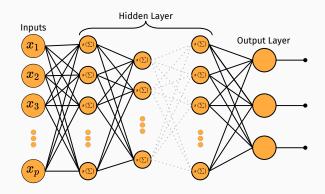

Singlelayer Perceptron

- Weighted sum of input values transformed by an activation function s
- If s is the sigmoid function $(1 + \exp \sum)^{-1}$, then the perceptron does exactly the same as the logistic regression

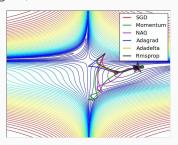

Multilayer Perceptron

- Stacking of multiple perceptrons
- Corresponds to stacking GLM models
- Number of parameter grows very fast
 - ightarrow Optimizing becomes more difficult

Optimizer

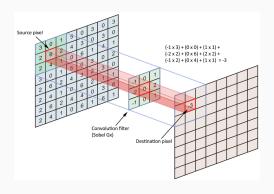

- Having that much parameter/weights to find, standard optimizer like Gradient Descent may fail
- Therefore, much effort was spend to get faster optimizer like momentum, adagrad, etc.:

Source: Ruder, S. (2016). An overview of gradient descent optimization algorithms. arXiv preprint arXiv:1609.04747.

Convolution

 Generating of new, hopefully meaningful, features of the input (commonly images)

Convolution

Generated Image/Feature

Note: The recognition of edges and corners requires a multiple application of the operator.

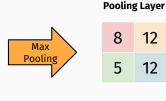

Pooling

- Down-sampling of images
- Reduces overfitting, memory usage, and therefore speeds up the fitting process

5 8 12 11 4 6 9 6 5 3 7 9 4 2 10 12

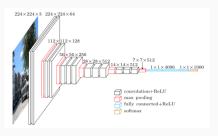

Input

Lets Get Deep

- The secret of Deep Learning is the chaining of hidden layer such as convolution layers, pooling layers, and so on
- This deep structure allows the network to create powerful features and explore complex structures within the data
- VGG16 architecture:

Challenges in Deep Learning

Challenges in Deep Learning

Architecture Search

Having that much possibilities of combining hidden layer, optimizer, and activation functions we run into the problem of finding a good architecture.

ightarrow Transfer learning, use already trained models, adjust them to your data situation, and train (a subset of) the weights.

Expensive Training

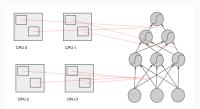

During the tuning of Deep Neural Networks requires billions of matrix multiplications, hence training **one** DNN might take weeks.

ightarrow Use GPU server for serious applications. Why? See next slides.

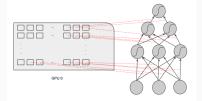

About Implementations

Hardware

- Deep Neural Networks require special hardware to be trained efficiently.
- The training is done using Graphics Processing Units and a special programming language called CUDA.
- Training on standard CPUs takes a very long long time and gets infeasible for anything but toy examples.

Each CPU can do 2-8 parallel computations.

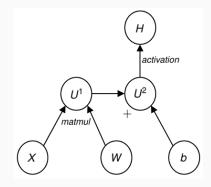

A single GPU can do thousands of simple parallel computations.

Software

CUDA is a very **low level** programming language and thus writing code for Deep Learning requires a lot of work. Software projects, like TensorFlow and abstract CUDA provide additional functionality.

The basic concept of calculations in deep neural networks is a *computational graph*, which describes the dependency structure of the network.

Computational graph for f(XW + b).

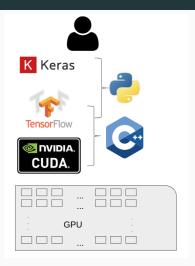

- Open-source framework developed by google.
- Rather low-level and aimed to directly work with computational graphs.
- Mainly support for Python (R support only via reticulate).
- Widely used and well documented.

- Open-source high-level API for Deep Learning.
- Can run on top of TensorFlow, CNTK or Theano.
- Mainly support for Python (R support only via reticulate).
- Widely used and well documented.

Keras in R

- Deep learning in R is the same as in Python.
- Communication from R to Python via **reticulate**.

Keras in R

- Syntax is (almost) identical.
- Same functionality.
- Same speed (slight overhead for communication between R and Python).
- More difficult to debug.

Useful resources:

https://keras.rstudio.com/

https://rstudio.github.io/reticulate/articles/introduction.html

PYTORCH

- Open-source framework developed by facebook.
- Reimplementation of Torch.
- Only support for Python.
- Widely used and well documented.

- Open-source high-level API build on top of PyTorch.
- Still in alpha version.
- Only support for Python.
- Initially developed for the Practical Deep Learning for Coders online course.

- Open-source framework in the Apache foundation.
- Scalable, allow easy training on multiple GPUs in parallel.
- Supports multiple languages (C++, Python, R, Julia, Matlab, JavaScript, Go, Scala, Pearl).
- Not as widely used as other frameworks.

Where to Start in the DL Jungle

Getting Started with Keras - Installation

Install keras using pip (or pip3 for python3) from the command line:

```
# python
pip install --upgrade tensorflow
pip install keras

# python3
pip3 install --upgrade tensorflow
pip3 install keras
```

On linux you may need to run the commands as sudo.

Getting Started with Keras - Overview

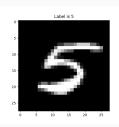

- Instead of introducing theory fist, we want to get into the topic by applying it.
- We use examples from the book Deep Learning with Python which are prepared as notebooks.
- But: When using something new, e.g. a convolution layer or optimizer, try to understand what it does and why it might be beneficial!

Getting Started with Keras - Example Data

```
import keras # equal to Rs library command
from keras.datasets import mnist
import matplotlib.pyplot as plt

(train_images, train_labels), (test_images, test_labels) = mnist.load_data()

plt.title('Label is {label}'.format(label=train_labels[3141]))
plt.imshow(train_images[3141], cmap='gray')
plt.show()
```

Getting Started with Keras - Example Data

We need to define in keras the shape of the images. Therefore, reshaping the images to 28×28 pixels.

```
train_images = train_images.reshape((60000, 28 * 28))
train_images = train_images.astype('float32') / 255

test_images = test_images.reshape((10000, 28 * 28))
test_images = test_images.astype('float32') / 255
```

Additionally, we have to convert the labels to a categorical data type:

```
from keras.utils import to_categorical

train_labels = to_categorical(train_labels)
test_labels = to_categorical(test_labels)
```

Getting Started with Keras - First Neural Net 1

Imports the Sequential model which is a linear stack of layers:

from keras import models

Imports the layers that can be used within the Sequential model:

from keras import layers

Getting Started with Keras - First Neural Net 2

```
network = models.Sequential()
# Add fully connected hidden layer:
network.add(layers.Dense(units=512,
                         activation='relu'.
                         input_shape=(28 * 28,)))
# Add output layer which maps each category to a neuron:
network.add(layers.Dense(10, activation='softmax'))
# Make the network ready for training:
network.compile(optimizer='rmsprop',
                loss='categorical crossentropy',
                metrics=['accuracy'])
# Train network:
network.fit(train images, train labels, epochs=5, batch size=128)
```

Getting Started with Keras - First Neural Net 3

Predict a new image:

Evaluate trained network:

```
network.evaluate(test_images, test_labels)
# [0.06617570319068618, 0.9798]
```
